## Sum of Ranking Differences (SRD)

- SRD is a novel statistical test that compares solution through a reference (Héberger, 2010).
- SRD is rapidly gaining popularity in science. Applications ranging from machine learning, through multi-criteria decision-making and pharmacology, to political science, and even sports.

## The model

- $M$ is an $n \times m$ matrix,
- where the first $m-1$ columns represent the different models,
- while the rows represent the measured variables (properties);
- the last column contains the reference values.

## Example input

## SRD step by step

(1) Defining the reference (data fusion)
(2) Rank transformation of the input
(3) Computing the SRD values for the solutions (distance from the reference)
(4) Validation (CRRN and cross-validation)

## 1. Reference values

SRD requires a reference value for each object. In some cases, justified reference values are available (prescriptions, earlier measurements). In the absence of a known gold standard, these reference values have to be extracted from the data. This step is called the data fusion. Most common reference values are:

- Known gold standard
- Average (arithmetic mean)
- Minimum/maximum
- Median

## 2. Converting the data matrix

- We create a ranking matrix by replacing each value in the column by its rank.
- That is, for each column (including the reference) take the smallest value in the column and replace it with ' 1 ', take the second smallest value and replace it with ' 2 ', and so on. Finally, the last remaining value, which was the largest of the original column values, is replaced by ' $n$ '.
- Ties in column vectors are resolved by giving the same rank to cells with the same value: the arithmetic mean of the ranks.

## 3. Computing the SRD values

- We calculate the (absolute) ranking differences between the reference and solution vector coordinates and sum them up.
- The SRD values are, in fact, city block (Manhattan) distances, and they rank the solutions.
- The smaller the SRD value the closer the solution is to the benchmark, i.e. the better.
- The mutual proximity of SRD values indicates the specific grouping of variables.

## 4. Validation

- To remain comparable within various data sets (and different number of rows) the normalized SRD values are calculated.
- The permutation test (also called randomization test, denoted by CRRN $=$ comparison of ranks with random numbers) shows whether the rankings are comparable with a ranking taken at random or they are different from it significantly.
- The second validation option is called cross-validation, and assigns uncertainties to the SRD values. Leave-one-out cross-validation is applied if the number of rows is less than 14. Leave-many out cross-validation is applied for larger number of rows in the input matrix.

## Fair representation

## The problem

In most democratic countries, some or all members of the Parliament are elected directly by the voters in electoral districts or (single-member) constituencies. For practical considerations these constituencies are embedded in the countries' existing administrative units, such as states or counties. To ensure equal representation, states are allotted seats in proportion to their populations. There are two related problems:

- How to distribute the seats among the administrative regions? (apportionment)
- How to design the constituencies, that is, how to draw the boundaries? (gerrymandering)

## Apportionment in fair representation

## Difficulties

- The division problems stems from the fact that fractional seats cannot be allocated (indivisible objects).
- The sizes of the constituencies should be roughly the same. Under ideal circumstances, every constituency contains the same number of voters.
- Constituency boundaries may be affected by the geography of the region, by administrative or historic boundary lines, or because of the concentration of a specific national minority.

## Gerry-salamander

Figure: Elbridge Gerry választókörzete

Gerrymandering: the manipulation of the constituency boundaries to favor one political party

## Example - Gerrymandering

## Exercise

Suppose two parties compete in a region where there are three electoral districts. The supporters of the two parties are equal in numbers but concentrate on different areas of the region. Let us assume that population are spread homogeneously on the map as follows

Create districts that favor one of the parties! How can we achieve fair representation?

## Gerrymandering

## Solution

## Compactness - Gerrymandering

Kansas

Gerrymandering

## Compactness measures

## CRRN - Gerrymandering

## Cross-validation

We create $k$ folds by leaving out some of the rows, then re-calculate the SRD values. The obtained scores are tested with the Wilcoxon signed rank test.

## Case study I - Food laboratories

- Laboratories participate in a comparison program, where they have to determine some characteristics of a homogeneous sample under documented conditions.
- Polycyclic Aromatic Hydrocarbon contents in 16 edible oil samples were reported by each participating laboratory.
- Since the laboratories work with the same substances, the laboratories should report the same measurements (within a small statistical error).
- Reference values were provided by the European Union Reference Laboratory for PAHs in food (EU-RL-PAH).

## Case study I - Food laboratories

## Case study II - Chess

- Elo ratings of the participants of the Grand Swiss tournament of 2019
- Data: Pre- and post tournament Elo ratings and tournament performance
- Post tournament ratings are the best approximations for the current playing strength of the players, hence it is chosen as the reference.
- Preliminary ratings and tournament performances are two perturbations of different amplitude - CV methods should be able to distinguish between the two.

## Case study III - Influence maximization

- In the influence maximization problem we are trying to optimize a network diffusion (e.g. innovation spreading)
- In the original version we aim to find the $k$ most influential persons, whose activation (by a marketing campaign) would incite the largest influence spread in the network.
- Here we try to assess the influence of groups instead of individuals. A real life example would be when a politician tries to decide which towns to visit in a campaign.
- question: which network centrality could predict the influence spread the best?

## Case study III - Influence maximization
